

Based on the document provided, the system is designed with three specific user roles. There is no separate "Planner" role; instead, the planning tasks are handled by the Admin.

+3

Here is a breakdown of the three roles and how the system flow works from start to finish.

The Three User Roles

You only need to input and manage these three types of users:

Admin: The primary "manager" of the system. This user handles procurement planning, project creation, supplier verification, bid evaluation, and final awarding.

+2

Supplier: External businesses that register, upload legal documents, and submit their price quotations/bids for specific projects.

Viewer/Public User: Any member of the public or school community who wants to verify that the bidding was fair by checking the blockchain records.

+3

The Complete System Workflow

The process follows a linear path from the initial request to the final blockchain record:

1. Project Setup (Admin)

The Admin starts by creating a Procurement Request. They input the project details, such as technical specifications (e.g., 20 Desktop Computers), the budget (e.g., ₱500,000), and the schedule. Once ready, the Admin publishes the project to make it visible to suppliers.

+4

2. Supplier Readiness

Suppliers must register on the platform and upload their legal documents. The Admin then reviews these profiles to Approve or Reject them based on their requirements. Only approved suppliers can see and bid on the available projects.

+4

3. Bidding Phase (Supplier & System)

Approved suppliers submit their bid proposals and quotations online. The system automatically records a timestamp for every submission to ensure no one can submit a bid after the deadline has passed.

+3

4. Evaluation & Awarding (Admin & System)

Once the deadline hits, the Admin compares the bids. The system assists by automatically ranking the suppliers based on your criteria. The Admin then selects the winner and the system generates the necessary legal paperwork, such as the Notice of Award and Notice to Proceed.

+4

5. Blockchain Integration (System & Public)

This is the final security step. After the winner is chosen, the system automatically saves the Project ID, Winning Supplier, Bid Amount, and Timestamp into the Blockchain Module.

+1

This generates a unique Hash Value. Because it is on a blockchain, the record becomes "tamper-evident"—if someone tries to change the data later, the hash will no longer match, alerting everyone to the unauthorized change. Finally, Public Users can use the verification page to view these results and ensure the process was honest.
